The present invention generally relates to computer systems and, more particularly, to techniques for system data recovery in computer systems. In a typical computer system a software application writes data to a disk drive. In a RAID system a shared disk drive is logically divided into a plurality of “virtual” disk drives by software. Certain software reads data from a virtual disk drive and writes the data into a physical disk drive. In the recent years, there is a growing demand for data recovery techniques in order to meet new needs in computer systems, such as high reliability systems, distributed systems, and the like. Computer systems having such a need for data recovery may be subject to a so-called “dark” or “data sudden loss”, where a failure in the system may leave the data on any disk drive inaccessible and unrecoverable. Such a scenario may be disastrous for an enterprise's productivity and may necessitate a reinstallation of the software application. Some data recovery techniques, including implementing high-speed RAID mirroring or fast backup methods to capture data prior to system failure, may provide some level of data recovery. However, such methods may only recover data that was already written to the disk at some point in time. Further, such methods may result in a software application becoming incompatible with an existing data storage system. Another approach to data recovery is based on providing mechanisms for detecting “faults” in the system. For example, most computer systems include a system board that has a plurality of system components interconnected by the cable. After a system failure, a “hot swapping” technique may be used to quickly connect another system board to the first board that may result in the system failure. However, once a system failure occurs, it may be very difficult to discern whether the fault is due to the system board or due to another fault in the system, such as a faulty system component. Thus, it may be desirable to perform “fault detection” procedures prior to rebooting the system or detecting “faults” in the system. Another concern with system data recovery is an availability of data. A common requirement of data storage systems is that users may obtain their stored data in less than a second. Thus, any system data recovery mechanism or technique that may be time consuming may jeopardize data availability. Accordingly, it would be desirable to provide a system that provides quick and efficient data recovery in the case of a system failure. In addition, it would be desirable
