Shellcode is a type of malicious code that attackers use to implant keylogging, eavesdrop, redirect, or perform other basic malicious tasks. Windows 10 adds a number of mitigations and address-space randomization techniques to prevent or limit an attacker's ability to chain together shellcode executions. Attacks that execute only a few specific functions, such as just displaying text, can be prevented by preventing targeted code execution, while others, such as running arbitrary code with administrative privileges, cannot be prevented. Windows 10 also introduces many other mitigations in the form of security certificates, data isolation, and hardware-enforced boundaries. Data on the system can be encrypted with a content-encryption key (CEK) or provisioned with hardware security modules (HSM) to protect the confidentiality of data on the system. Isolation technology is used to prevent functionality and data sharing between processes and operating system components. For example, when a malicious process is prevented from using a range of APIs, it cannot communicate or share data with other Windows components. Windows 10 includes advanced effort security features, such as stealthy sleep attacks. A user who is asleep in a notebook or desktop computer can trigger stealthy sleep attacks against Windows. Windows 10 is also resistant to this threat.
